

Objective

Deliver the final version of your project, plus a video.

The submission is done via Moodle by just **one element of the group**. If more than one element submits, we will just consider the most recent submission.

You need to submit **on October 24 until the end of the day (23:59)**.

Moodle will lock submissions at that time, so make sure you give yourself enough time to upload.

Projects delivered **late will not be graded** (***you will fail the course***).

Requirements/Deliverables

For this final submission you need to prepare two things:

1. **A folder containing your project.** It should be ready to run as-is: just unzip to a local folder, open a local server and we're ready to go! It must include all scripts, data files, etc. Any special requirements/instructions should be given in a README.txt file. This cannot include the installation of servers, access to remotely hosted services, etc. Avoid any external dependencies. If you need them, download and use them locally. Again: I turn off the Internet, unzip, open a local file and everything works. Also, you should always use d3 version 7. **You will be penalized for each different version used within the project.**
2. **A video file (h264 codec, MP4 format), between 2 and 3 minutes, demonstrating your project.** You have seen several throughout the lectures so you know what is expected but, in a nutshell: the first part should describe the visualization, its different components, and how it works. The second should highlight some use cases and demonstrate its usefulness vis-à-vis the questions you defined in the first checkpoint. You can look at examples of good videos in the course's **Hall of Fame**.

Not following the required formats: ZIP for the file (not 7ZIP, not ARJ, not LHA, ...) or MP3/H264 for the video (not MKV, WEBM, WMV, ...) will be penalized with at least **one grade point** (for each fault...). However, in the worst case, if we are unable to promptly open the wrong format (we will not be searching for installing codec packs or other software "just for you"), you will get a zero on that component!

Create a zip file with the three things. The name should be:

"VI-<group>.zip".

For instance, Group 5 names the file “**VI-05.zip**”. Upload it to Moodle. For student workers: you don’t have a group number, please use your initials instead (ex: “VI-DG.zip”).

The project will be graded in due time and the grade posted on the page’s course.

Do note: there is an upload size limit on Moodle. Leave the upload to the last minutes at your own peril. If something goes wrong, the obvious fix will be to reencode the video at a different quality setting. If strictly necessary, you can include the URL for a high-quality version of the video in your README.txt file but the Moodle submission needs to be complete, even if you must include a low-quality version in it. Having said this, if you’re needing to go over the limit for a 3min video, you’re doing it wrong...

Again, for the final time, **you are only allowed to use D3.js**. No other frameworks are permitted. This means do not use React, Angular, Node.js, or any similar tools to simplify development. If you do, your checkpoint will receive a **grade of 0**. You may use Python for the backend, if necessary, but your frontend must be built using only plain JavaScript, HTML, and CSS

Penalties

- Use of d3 versions other than version 7: **2 grade points penalty for each different version**.
- Existence of external dependencies: **2 grade points penalty for each dependency (max 4 points discount)**.
- Videos under or over time: **1 grade point**.
- Not following the required formats: **1 grade point penalty for each wrong format**.
- Zip with project and video uploaded after the deadline: **YOU WILL FAIL THE COUSE**.

Grading

Your work will be graded according to the following parameters:

Prototype [80%]

- **Completeness** (answers the tasks from CPI)
- **Adequacy** (the visual idioms used are adequate for what they are trying to depict)
- **Understandability** (without learning, it should be easy to explore the dashboard)
- **Integration** (all visual idioms work well together. There is a complete data exploration)
- **Data Exploration & Sophistication** (Visually polished and takes advantage of the dataset)
- **Layout & graphic design** (the dashboard feels visually consistent with fit design principles)
- **Interactivity** (all idioms are interactive. It is possible to explore data through them)
- **Creativity** (some dashboard may go to infinity and beyond. This will be valued)

Video [20%]

- Duration
- **Explanation of the visualizations** (after watching the video, I know how the dashboard works)
- **Demonstration of usefulness** (show some tasks from CPI being answered)
- “Standaloneness” (i.e., if someone just watches the video, no prototype, is the project understandable?)
- Technical quality (no audio or low-quality audio? Can’t barely read the text in the text in the legends? Compression artefacts?)
